## Measures of Dispersion

This gives a measure of the dispersion of the observation around the measure of central tendency of the data collected.

### Range

Range of a data = Maximum value – Minimum value.

### Mean Deviation

Mean deviation of central tendency 'a' of a data is given by

$$M.D(a) = \frac{\text{Sum of absolute values of deviations from 'a'}}{\text{Number of observations}} - \text{Mean}(\bar{x}) = \frac{\sum_{i=1}^n f_i x_i}{\sum_{i=1}^n f_i}$$

- **Ungrouped data**

Mean deviation for the data  $x_1, x_2, x_3, \dots, x_n$  is

$$M.D(a) = \frac{\sum_{i=1}^n |x_i - a|}{n}$$

$$- \text{Mean}(\bar{x}) = \frac{\sum_{i=1}^n x_i}{n}$$

– Median is  $\frac{n+1}{2}^{th}$  term when n is odd  
– mean of  $\frac{n}{2}^{th}$  and  $\frac{n}{2} + 1^{th}$  term when n is even

- **Grouped Discrete frequency distribution**

Mean deviation for the data  $x_1, x_2, \dots, x_n$  occurring with frequencies  $f_1, f_2, \dots, f_n$  respectively is

$$M.D(a) = \frac{\sum_{i=1}^n f_i |x_i - a|}{\sum_{i=1}^n f_i}$$

$$- \text{Mean}(\bar{x}) = \frac{\sum_{i=1}^n f_i x_i}{\sum_{i=1}^n f_i}$$

– To find the median form a column for cumulative frequencies

- **Grouped Continuous frequency distribution**

A continuous frequency distribution is a series in which the data are classified into different class-intervals without gaps alongwith their respective frequencies.

To find the Mean deviation about a central tendency 'a', choose  $x_i$  as midpoint of the intervals and convert it into Discrete.

$$- \text{median} = l + \frac{c(\frac{N}{2} - f_0)}{f_1}$$

$l$  - lower limit of the median class  
 $f_0$  - Cumulative frequency of the class preceding the median class.

$f_1$  - Cumulative frequency of the median class.

$c$  - width of the interval

$$N - \sum_{i=0}^n f_i$$

### Shortcut method for finding the mean of frequency distribution

1. Select an assumed mean 'a' (value close to middle)
2. subtract assumed mean from each  $x_i$
3. choose appropriate h and divide each  $x_i - a$  by h and define it as  $d_i$
4. find mean using the formula

$$\bar{x} = a + \frac{\sum_{i=1}^n f_i d_i}{N} \times h$$

## Variance and Standard Deviation

standard deviation =  $\sqrt{\text{variance}}$

---

## Ungrouped Data

variance for the data  $x_1, x_2, x_3, \dots, x_n$  is

$$\sigma^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$$

## Grouped frequency distribution

Variance for the data  $x_1, x_2, \dots, x_n$  occurring with frequencies  $f_1, f_2, \dots, f_n$  respectively is

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^n f_i (x_i - \bar{x})^2$$

## Another formula for standard deviation

$$\sigma = \frac{1}{N} \sqrt{N \sum_{i=1}^n f_i x_i^2 - \left( \sum_{i=1}^n f_i x_i \right)^2}$$

## Shortcut method to find variance and standard deviation

Let the assumed mean be 'A' and the scale be reduced to  $\frac{1}{h}$  times (h being the width of class-intervals). Let the step-deviations or the new values be  $y_i$ .

$$y_i = \frac{x_i - A}{h}$$

then

$$\sigma = \frac{h}{N} \sqrt{N \sum_{i=1}^n f_i y_i^2 - \left( \sum_{i=1}^n f_i y_i \right)^2}$$
